Abstract

The city of Warsaw was razed at the end of World War II and rebuilt under a socialist government whose policy was to allocate dwellings, schools, and health facilities without regard to social class. Of the 14,238 children born in 1963 and living in Warsaw, 96 percent were given the Raven's Progressive Matrices Test and an arithmetic and a vocabulary test in March to June of 1974. Information was collected on the families of the children, and on characteristics of schools and city districts. Parental occupation and education were used to form a family factor, and the district data were collapsed into two factors, one relating to social marginality, and the other to distance from city center. Analysis showed that the initial assumption of even distribution of family, school, and district attributes was reasonable.

Despite a century of research on complex traits in humans, the relative importance and specific nature of the influences of genes and environment on human traits remain controversial. We report a meta-analysis of twin correlations and reported variance components for 17,804 traits from 2,748 publications including 14,558,903 partly dependent twin pairs, virtually all published twin studies of complex traits. Estimates of heritability cluster strongly within functional domains, and across all traits the reported heritability is 49%. For a majority (69%) of traits, the observed twin correlations are consistent with a simple and parsimonious model where twin resemblance is solely due to additive genetic variation. The data are inconsistent with substantial influences from shared environment or non-additive genetic variation. This study provides the most

Significance

Differences among children in educational achievement are highly heritable from the early school years until the end of compulsory education at age 16, when UK students are assessed nationwide with standard achievement tests [General Certificate of Secondary Education (GCSE)]. Genetic research has shown that intelligence makes a major contribution to the heritability of educational achievement. However, we show that other broad domains of behavior such as personality and psychopathology also account for genetic influence on GCSE scores beyond that predicted by intelligence. Together with intelligence, these domains account for 75% of the heritability of GCSE scores. These results underline the importance of genetics in educational achievement and its correlates. The results also support the trend in education toward personalized learning.

Genetic and environmental determinants of violence risk in psychotic disorders: a multivariate quantitative genetic study of 1.8 million Swedish twins and siblings

A Sariaslan¹, H Larsson² and S Fazel¹

Patients diagnosed with psychotic disorders (for example, schizophrenia and bipolar disorder) have elevated risks of committing violent acts, particularly if they are comorbid with substance misuse. Despite recent insights from quantitative and molecular genetic studies demonstrating considerable pleiotropy in the genetic architecture of these phenotypes, there is currently a lack of large-scale studies that have specifically examined the aetiological links between psychotic disorders and violence. Using a sample of all Swedish individuals born between 1958 and 1989 ($n = 3\,332\,101$), we identified a total of 923 259 twin-sibling pairs. Patients were identified using the National Patient Register using validated algorithms based on International Classification of Diseases (ICD) 8–10. Univariate quantitative genetic models revealed that all phenotypes (schizophrenia, bipolar disorder, substance misuse, and violent crime) were highly heritable ($h^2 = 53–71\%$). Multivariate models further revealed that schizophrenia was a stronger predictor of violence ($r = 0.32$; 95% confidence interval: 0.30–0.33) than bipolar disorder ($r = 0.23$; 0.21–0.25), and large proportions (51–67%) of these phenotypic correlations were explained by genetic factors shared between each disorder, substance misuse, and violence. Importantly, we found that genetic influences that were unrelated to substance misuse explained approximately a fifth (21%; 20–22%) of the correlation with violent criminality in bipolar disorder but none of the same correlation in schizophrenia ($P_{\text{bipolar disorder}} < 0.001$; $P_{\text{schizophrenia}} = 0.55$). These findings highlight the problems of not disentangling common and unique sources of covariance across genetically similar phenotypes as the latter sources may include aetiologically important clues.

Childhood family income, adolescent violent criminality and substance misuse: quasi-experimental total population study

Amir Sariaslan, Henrik Larsson, Brian D’Onofrio, Niklas Långström and Paul Lichtenstein

Background

Low socioeconomic status in childhood is a well-known predictor of subsequent criminal and substance misuse behaviours but the causal mechanisms are questioned.

Aims

To investigate whether childhood family income predicts subsequent violent criminality and substance misuse and whether the associations are in turn explained by

Results

Children of parents in the lowest income quintile experienced a seven-fold increased hazard rate (HR) of being convicted of violent criminality compared with peers in the highest quintile (HR=6.78, 95% CI 6.23–7.38). This association was entirely accounted for by unobserved familial risk factors (HR=0.95, 95% CI 0.44–2.03). Similar pattern of effects was found for substance misuse.

(education, employment, wages, housing, mental health, substance abuse and criminality) is sparse. Using the PRISMA method, the outcomes of 32 original quantitative studies were compared. The studies were categorized into two groups reflecting on the child welfare orientation of the country: child protection vs. family service (Gilbert, Parton, & Skivenes, 2011). The results are clear as well as troubling. In both systems, children who leave care continue to struggle on all areas (education, employment, income, housing, health, substance abuse and criminal involvement) compared to their peers from the general population. A stable foster care placement, establishing a foothold in education and having a steady figure (mentor) who supports youth after they age out of care seem to be important factors to improve the outcomes.

Children and Youth Services Review

Children in out-of-home care as young adults: A systematic review of outcomes in the Nordic countries

Antti Käariälä ^a, Heikki Hiilamo ^{a, b}

Of 333 studies identified, 20 met the inclusion criteria. All of these studies were cohort studies that employed social and health register data. OoHC placement was studied with nine outcome categories: self-supporting problems, educational challenges, mental health problems, criminality, teenage parenthood, mortality, suicidal behavior, alcohol and drug use, and disability pension. In each of these categories, young adults with a history in OoHC faced higher risks compared with the general population, even after adjusting for various birth parents' socio-economic, demographic, and mental health-related factors.

Abstract

When a child is removed from their home and placed in foster care, society takes over the responsibility for that child's well-being and development. Failure to provide a child with a nurturing upbringing may have negative consequences for the child as well as for society. Using Swedish longitudinal registry data for a national cohort sample of siblings, in which some were placed in foster care and others remained in their birth parents' care, this study asks whether long-term foster care ensures improved life chances. Results from multilevel regression analyses of a wide range of educational, social, and health-related outcomes in mature adult age (16 outcome constructs) support a row of previous studies indicating that traditional long-term foster care does not seem to improve maltreated children's life chances.

Keywords

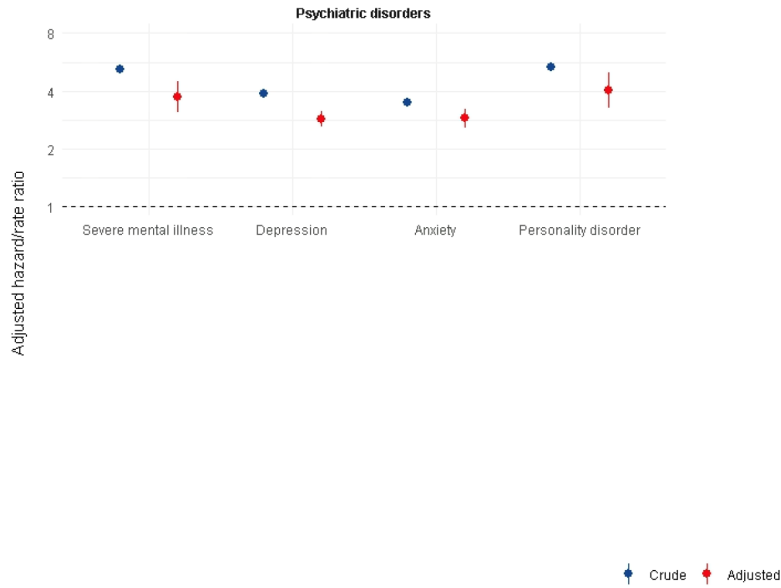

foster care, longitudinal research, long-term effects, siblings

Metodologiska begränsningar:

- Små urval (n ~ 1000)
- Begränsad group (Långtidsplaceringar)
- Syskon inkluderade maternella halvsyskon

Triggers for Violent Criminality in Patients With Psychotic Disorders

Amir Sariaslan, PhD; Paul Lichtenstein, PhD; Henrik Larsson, PhD; Seena Fazel, MD

IMPORTANCE Absolute and relative risks of violence are increased in patients with psychotic disorders, but the contribution of triggers for violent acts to these risks is uncertain.

OBJECTIVE To examine whether a range of triggers for violent acts are associated with risks of violence in patients diagnosed with psychotic disorders and in individuals without a psychiatric diagnosis.

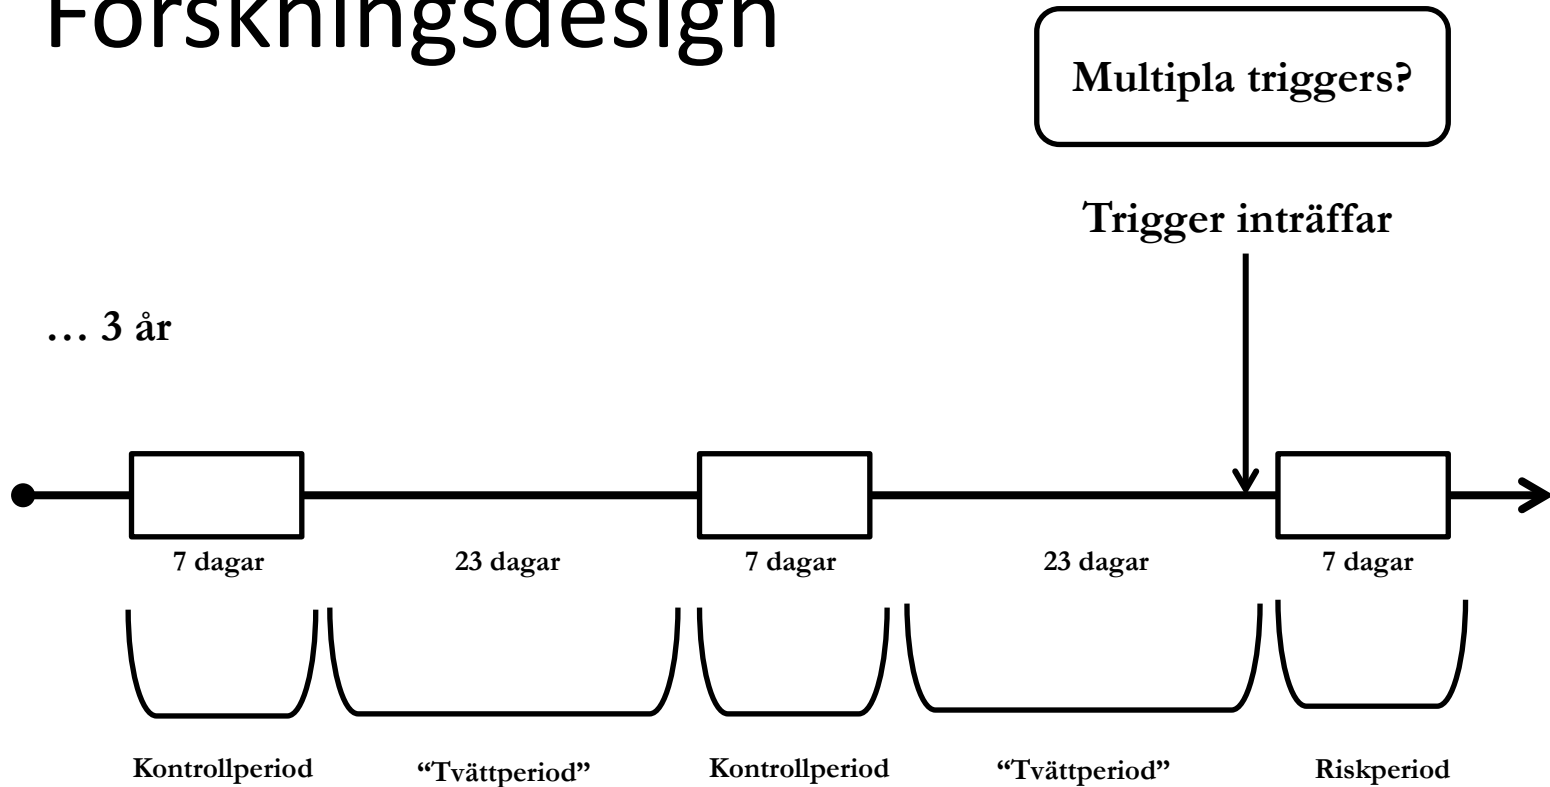

DESIGN, SETTING, AND PARTICIPANTS Using a sample of all individuals born in Sweden between 1958 and 1988 (N = 3 123 724), we identified patients in the National Patient Register who were diagnosed with schizophrenia spectrum disorders (n = 34 903) and bipolar disorder (n = 29 692), as well as unaffected controls (n = 2 763 012). We then
